What details in the visualizations informed your decisions?

(27 replies)

Skew, especially how it differed between the two populations. A significant difference in peak value. And also a general difference in shape (somewhat quantified by an indication of variance)

difference between the blue vs red line and the shapes and where the dots are

Mean, Peak Density, Weight.

The mean value, range, and shape of distribution

Higher peaks on the line graphs, median position in box plots

any drastic or clear variations from the general patterns in the data. outliers and mean values in the box plots, violin plots looking for dissimilar shapes

Mean in the box and violin plots, and the range of values as well as the shape and difference in groups in the density plots.

I looked for differences slight in shapes when looking at the line graphs, found the box plots rather difficult to figure out, but tried looking at the extreme values either side and looked for differences. I also tried to make use of the lines for the mean values and checked whether or not there were vast differences. The violin plots were also difficult to distinguish.

jarring lack of overlap

Shape

Naturally the color red took focus, any weird peaks in red mostly stood out. For box plot, the position of black line for median in one plot and the placement of red box relative to blue box in another. For funnel charts, it was more on the shape changes.

mostly just the general shape of the graph, meaning that I found the boxplots very hard to differentiate between

Difference between lines in plots, rough shape

For the boxplots I looked at the median. For the density plots I looked just at the shape and the overlap.

for the two curves it was whichever had the biggest disparity between red and blue - always pretty clear. the pink and blue blobs were harder, i did it based on things like whether the shapes had long tails or were stumpy. the box plots were very difficult indeed, it was to do with the line lengths and where the middle line was in each box. but also kind of just vibes

Shape, height, range, outliers, just seeing which one stood out.

Greater variation in plotted data

Absence of features present in other graphs

Big difference between groups. Lots of outliers in the box plots.

differences in the line plots, outliers and quantiles for box plots

Range / variance/ where the outliers are / looking at how each group individually varies across the 20 images

Usually the largest gap between groups

Outliers

For line graphs, the magnitude and location of the peaks of red and blue, and how they were related to other samples For Q1 and Q6 I looked at the cutoff points of the data as well as the position/magnitude of the largest/widest point on the diagram for each color For the box plots I looked mostly at the number of outliers and the thickness of the quartiles

After reviewing the graphs in each lineup, it's apparent that most share similar patterns. I selected the graph that differs the most from the average. The degree of similarity among the graphs influences how confident I feel about my choice.

Extreme points, such as the maximum and minimum values, the range of values, the average line and the Q1 and Q3 lines ()Extreme points, such as the maximum and minimum values, the range of values, the average line and the Q1 and Q3 lines (For box plot)

how much the two data sets differ from each other in each graph
